ACM REP '24 20 June 2024

Chemical physics: how many phases for supercooled water?

As it turned out, the trouble stemmed from the algorithmic trick the Berkeley team had used to speed up its code. Both teams had performed their free-energy calculations using Monte Carlo simulations, which can be used to find the low-energy states of a molecular ensemble by randomly sampling—and systematically accepting or rejecting—various potential ensemble configurations. To do Monte Carlo, you need an efficient way to generate those sample configurations. The Berkeley team chose to generate them by running short molecular dynamics simulations in which molecules were initialized with random positions and velocities.

The procedure the Berkeley team used to initialize the molecular dynamics simulations was unorthodox — it involved randomly selecting a pair of molecules and then swapping the velocities of their constituent atoms. Palmer and company discovered that the technique produced sample configurations that seemed to flout basic laws of statistical mechanics: The energies deviated from the expected equilibrium values, governed by the Boltzmann distribution, and the molecules' rotational and translational temperatures didn't match up. Perhaps most important, the molecules behaved as if they were tens of degrees hotter than their assigned temperature.

SOFTWARE ENGINEERING FOR CSE

Streamlining Development of a Multimillion-Line Computational Chemistry Code

Robin M. Betz and Ross C. Walker I San Diego Supercomputer Center

Software engineering methodologies can be helpful in computational science and engineering projects. Here, a continuous integration software engineering strategy is applied to a multimillion-line molecular dynamics code; the implementation both streamlines the development and release process and unifies a team of widely distributed, academic developers.

Betz & Walker, Comp. Sci. Eng. 16(3), 10-17 (2014)

nan

3

M.F. Jarrold, Phys. Chem. Chem. Phys. 9, 1659 (2007):

Molecular Dynamics (MD) simulations were performed to help interpret the experimental results. The simulations were done with the MACSIMUS suite of programs [31] using the CHARMM21.3 parameter set. A dielectric constant of 1.0 was employed.

A variety of starting structures were employed (such as helix, sheet, and extended linear chain) and a number of simulated annealing schedules were used in an effort to escape high energy local minima. Often, hundreds of simulations were performed to explore the energy landscape of a particular peptide. In some cases, MD with simulated annealing was unable to locate the lowest energy conformation and more sophisticated methods were used (see description of evolutionary based methods below).

3

M.F. Jarrold, Phys. Chem. Chem. Phys. 9, 1659 (2007):

Molecular Dynamics (MD) simulations were performed to help interpret the experimental results. The simulations were done with the MACSIMUS suite of programs [31] using the CHARMM21.3 parameter set. A dielectric constant of 1.0 was employed.

This is a typical level of description!

A variety of starting structures were employed (such as helix, sheet, and extended linear chain) and a number of simulated annealing schedules were used in an effort to escape high energy local minima. Often, hundreds of simulations were performed to explore the energy landscape of a particular peptide. In some cases, MD with simulated annealing was unable to locate the lowest energy conformation and more sophisticated methods were used (see description of evolutionary based methods below).

Beyond Programming Languages

Terry Winograd Stanford University

As computer technology matures, our growing ability to create large systems is leading to basic changes in the nature of programming. Current programming language concepts will not be adequate for building and maintaining systems of the complexity called for by the tasks we attempt. Just as high level languages enabled the programmer to escape from the intricacies of a machine's order code, higher level programming systems can provide the means to understand and manipulate complex systems and components. In order to develop such systems, we need to shift our attention away from the detailed specification of algorithms, towards the description of the properties of the packages and objects with which we build. This paper analyzes some of the shortcomings

Introduction

Computer programming today is in a state of crisis (or, more optimistically, a state of creative ferment). There is a growing recognition that the available programming languages are not adequate for building computer systems. Of course, as any first year student of computation theory knows, they are logically sufficient. But they do not deal adequately with the problems we face in the day-to-day work of programming. We become swamped by the complexity of large systems, lost in code written by others, and mystified by the behavior of our almost debugged systems. When we look to the integrated multiprocessor systems that will soon dominate computing, the situation is even worse.

Lotka-Volterra equations

Numerical simulation: the symplectic Euler method

A common strategy for stabilizing numerical solutions is to switch to an *implicit* integration scheme, in which the quantities on the right-hand side are evaluated at the *endof* the step rather than at the *degining*. Doing this would result in the *implicit Euler method*. As explained in the blog post cited before, the best strategy for the Lotka-Volterra equations is to apply this strategy to only one of the to quantities (we hoose 3), resulting in the *symplectic Euler method*.

Ē -

We define the solutions obtained with the symplectic Euler method as $xas : (N \rightarrow R)$ and $yas : (N \rightarrow R)$ with the rules:

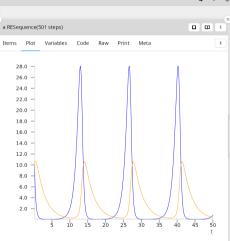

```
lvx/symplectic: \underline{n}: \mathbb{N}.nz, xas[\underline{n}] \Rightarrow xas[\underline{n} - 1] + (1 - (\Delta t \times (\alpha - (\beta \times yas[\underline{n} - 1])
```

lvy/symplectic: $\underline{n}:N.nz$, $yas[\underline{n}] \Rightarrow yas[\underline{n} - 1] + (\Delta t \times ((\delta \times xas[\underline{n}] \times yas[\underline{n} - 1]))$

Back to the example

These equations yield the expected periodic cycles:

```
sequence3 := RESequence -
context: (thissinpet page - lzSubcontext: #example)
rules: #('lvx/symplectic' 'lvy/symplectic')
parameters: { 14t + 1/0 }
initialValues: (dictionary -
with: 'xas' → = #(10.0)
indevVariable: '+'
```

Application scenarios

Software documentation

- Embedded into prose written for humans
- Equivalence to papers/textbooks verified by human reviewers
- Equivalence to the code proven by formal methods

User interface

- Users write specializations etc. in a DSN
- Code generators translate to optimized code

Application scenarios

Software documentation

- Embedded into prose written for humans
- Equivalence to papers/textbooks verified by human reviewers
- Equivalence to the code proven by formal methods

User interface

- Users write specializations etc. in a DSN
- Code generators translate to optimized code

Computational medium

- Scientists do all their work in a Wiki-like environment
- Computational tools become plug-ins
- UI elements include DSN, visualizations, etc.

Computation is about formal systems

The most important boundary in scientific computing is between a **formal system** (\rightarrow reproducibility) and its **interpretation** (\rightarrow replicability).
